# Trading 1Min Bar Euro Futures Using The Fading Memory Polynomial Velocity Strategy <br> January 3, 2008 -Jun 28, 2019 <br> Working Paper June 2019 <br> Copyright © 2019 Dennis Meyers 

## Disclaimer

The strategies, methods and indicators presented here are given for educational purposes only and should not be construed as investment advice. Be aware that the profitable performance presented here is based upon hypothetical trading with the benefit of hindsight and can in no way be assumed nor can it be claimed that the strategy and methods presented here will be profitable in the future or that they will not result in losses

This is a mathematical technique that fits a $\mathrm{n}^{\text {th }}$ order polynomial to the last $\boldsymbol{T}$ price bars but calculates the coefficients of the polynomial such that the error between the current $\mathrm{n}^{\text {th }}$ order polynomial and the current bar is weighted much higher than the error between the price T bars ago and the value of the $\mathrm{n}^{\text {th }}$ order polynomial T bars ago. As an example, if the latest price is at time $t$ and the price made a turn at time bar $\mathrm{t}-10$, then we do not want prices prior to $\mathrm{t}-10$ affecting the current polynomial fit as much. As will be shown the most familiar case of this fading memory technique is the exponential moving average. The fading memory technique contrasts with the Least Squares Polynomial fit, which weights all past errors between the polynomial and the price bar equally.

In previous working papers at http://www.meyersanalytics.com/papers.php we showed how the application of a price curve generated by Nth Order Fixed Memory Polynomial Velocity could be used to develop a strategy to buy and sell futures intraday. The reasoning behind this type of system was to only trade when the price trend velocity was above a certain threshold. Many times, prices meander around without any notable trend and this is considered noise. During these times we do not wish to trade because of the cost of whipsaw losses that would occur from this type of price action. When a price trend finally starts, the velocity of that price trend moves above a minimum threshold noise value. Thus, the velocity system would only issue a trade when certain velocity thresholds above ñoiseòlevels are crossed.

The velocity system that we will use here to trade the Euro futures contract is called the Nth Order Fading Memory Adaptive Polynomial Velocity Strategy. The word ñAdaptiveò is used because the polynomial inputs change over time, adapting to the changing trading patterns of the Euro futures contract. The Nth Order Fading Memory Adaptive Polynomial Velocity Strategy has a number of unknown inputs that we have to determine before we can use this strategy to trade. These unknown inputs to the Fading Memory Polynomial are the polynomial order, the optimum number of prices we need to determine the coefficients of the polynomial and finally the velocity thresholds. Here we will use Walk Forward Optimization and out-of-sample performance to determine the f̃bestò polynomial inputs as well as how these inputs should change over time. We will use the nth Order Fading Memory Adaptive Polynomial Velocity System to trade the Euro futures contract on an intraday basis using one-minute bar price data. To test this strategy, we will use one-minute bar prices of the Euro futures contract (EC) traded on the CME/Globex from January 3, 2008 to June 28, 2019.

## The $n^{\text {th }}$ Order Fading Memory Adaptive Polynomial Velocity Defined

The adaptive $\mathrm{n}^{\text {th }}$ order Fading Memory Polynomial Velocity is constructed and plotted at each bar by solving for the coefficients $\mathbf{b}_{\mathbf{1}}, \mathbf{b}_{\mathbf{2}}, \mathbf{b}_{3}, \ldots \mathbf{b}_{\mathbf{n}}$ for the discrete orthogonal Meixner polynomials at each bar using the exponential decay factor $\boldsymbol{\alpha}=(\mathbf{1}-\boldsymbol{\beta})$ and the equation for $\mathbf{b}_{\mathbf{j}}$ shown in the "Math" appendix of this paper. Then $\operatorname{Velocity}(\mathbf{T}+\mathbf{1})$ is constructed from the equation shown in the ñMathò appendix and plotted under the price chart.

The velocity of a $2^{\text {nd }}$ order polynomial should change faster than the straight line ( $1^{\text {st }}$ order velocity). As observed from the $2^{\text {nd }}$ order velocity equation in the $\tilde{\text { ñ Mathò section, there is an }}$ acceleration component in the calculation of the velocity. This means that the $2^{\text {nd }}$ order velocity will reflect a change in the price trend much faster than the straight-line velocity which does not have an acceleration component.

At each bar we calculate the $2^{\text {nd }}$ order fading memory polynomial velocity from the formulas in the ñMathò appendix. When the velocity is greater than the threshold amount vup we will go long. When the velocity is less than the threshold amount $\boldsymbol{v} \boldsymbol{v} \boldsymbol{d} \boldsymbol{n}$ we will go short.

## Buv Rule:

IF Velocity is greater than the threshold amount $\boldsymbol{v} u \boldsymbol{p}$ then buy at the market.

## Sell Rule:

IF Velocity is less than the threshold amount $\boldsymbol{- v} \boldsymbol{d} \boldsymbol{n}$ then sell at the market.

The strategy follows the velocity curve. When the velocity is greater than the threshold amount vup a buy signal is issued. The threshold vup serves as a noise filter. That is, price noise creates a lot of small back and forth velocity movement. Unless the velocity can break some threshold to the upside, no trade is issued, and the move is considered price noise. The same logic holds for the sell threshold vdn.

## Intraday Bars Exit Rule:

Close the position at 1350 when U.S trading dies down. (no trades will be carried overnight). Note: Before July 2015 floor trading stopped at 1400 CST

## Intraday Bars First Trade of Day Entry Rule:

Ignore all trade signals before 7:00am. For the Buy and Sell rules above we have included a first trade of the day entry rule. Trading in the EC futures has changed a lot in the last 7 years because of 24hr Globex trading. Trading starts a lot earlier in the morning when Asia and then Europe opens and then dies down. The EC volume starts to pick up again around 7am CST here in the U.S. so we will have the strategy resume trading at 7 am .

## Discussion of Euro Prices

The Euro (EC) is traded on Globex. On Globex the EC is traded on a 23hour basis. The Old CME hours for floor trading (RTH) are 7:20 to 14:00 CST. Approximately Over $50 \%$ of the
volume in the EC is done on Globex during the Old CME RTH hours. We have restricted our study to only trading the EC during 7:00 to 1350 hours.

## Data Discussion

To test this strategy, we will use 1-minute bar prices of the Euro futures contract traded on the and known by the symbol $\boldsymbol{E C}$ for the 595 weeks from January 2, 2008 to June 28,2019.

We will test this strategy with the above EC 1 min bars on a walk forward basis, as will be described below. In TradeStation (TS) or MultiCharts (MC), we will run the FadmVn Strategy on the EC 1 min bar data from January 3, 2008 to June 28, 2019. We will breakup and create 30 -day calendar in-sample sections along with their corresponding one calendar week out-of-sample sections from the 595 weeks of EC (see Walk forward Testing below) creating 595 out-of-sample weeks.

To create our walk forward files we will use the add-in software product called the Power Walk Forward Optimizer (PWFO) http://meyersanalytics.com/Walk-Forward-Optimization.html . In TS/MC, we will run the PWFO strategy add-in along with the FadmVn Strategy on the EC 1min data from $1 / 3 / 2008$ to $6 / 28 / 2019$ The PWFO will breakup and create 30 -day calendar in-sample sections along with their corresponding one calendar week out-of-sample sections from the 595 weeks of EC (see Walk Forward Testing below) creating 595 out-of-sample weeks. Note the first in-sample week will be from $1 / 3 / 2008$ to $2 / 1 / 2008$ and the first out-of-sample week will be from 02/03/2008 to 02/08/08

## Testing the Polynomial Velocity System Using Walk Forward Optimization

There will be three strategy parameters to determine:
degree degree $=2$ for $2^{\text {nd }}$ order velocity.
alpha=(1- $\boldsymbol{\beta})$ The exponential decay weight for the Nth Order Fading Memory Polynomial calculation.
vup, the threshold amount that velocity must be greater than to issue a buy signal $\boldsymbol{v} \boldsymbol{d} \boldsymbol{n}$, the threshold amount that velocity must be less than to issue a sell signal

## What Is A Walk Forward Optimization with In-Sample Section and Out-Of-Sample Sections?

Whenever we do a TradeStation (TS) or MultiCharts (MC) optimization on a number of different strategy inputs, TS/MC generates an in-sample report of performance metrics (total net profits, number of losing trades, etc.) vs these different strategy inputs. If the report is sorted on say the total net profits(tnp) performance metric column then the highest tnp would correspond to a certain set of inputs. This is called an in-sample (IS) section. If we choose a set of strategy inputs from this report based upon some performance metric, we have no idea whether these strategy inputs will produce the same results on future price data or data they have not been tested on. Price data that is not in the in-sample section is defined as out-of-sample (OOS) data. Since the performance metrics generated in the in-sample section are usually mostly due to ñcurve fittingò or "data mining" it is important to see how the strategy inputs chosen from the in-sample section perform on out-of-sample price data.

What do we mean by "curve fitting" or data mining? As a simple example, suppose you were taking a subway to work. In the subway car you are in, suppose you counted the number of blond women in that car and suppose the percent of blond women vs all other women hair colors was $80 \%$. Being that you can't observe what is in the other subway cars, you would assume that all the other subway cars and perhaps all women in general had the same percentage of blond hair. This observation was due to chance. That is an example of curve fitting. The same goes for combinatorial searches. You are observing results from a finite sample of data without knowing the data outside the sample you examined.

Walk forward analysis attempts to minimize the curve fitting of price noise by using the law of averages from the Central Limit Theorem on the out-of-sample performance. In walk forward analysis the data is broken up into many in-sample and out-of-sample sections. Usually for any strategy, one has some performance metric selection procedure, which we will call a filter, used to select the input parameters from the in-sample optimization run. For instance, a filter example might be all cases that have a profit factor (PF) greater than 1 and less than 3 . For the number of cases left, we might select the case that had the best percent profit. This procedure would leave you with one case in the in-sample section and its associated strategy input parameters. Now suppose we ran our optimization on each of our many in-sample sections and applied our filter to each in-sample section. We would then use the strategy input parameters found by the filter in each in-sample section on the out-of-sample section immediately following that in-sample section. The strategy input parameters found in each in-sample section and applied to each out-of-sample section would produce independent net profits or losses for each of the out-of-sample sections. Using this method, we now have "x" number of independent out-of-sample section profit and losses from our filter. If we take the average of these out-of-sample section net profits and losses, then we will have an estimate of how our strategy will perform on average. Due to the Central Limit Theorem, as the number of out-of-sample sections increases, the spurious noise results in the out-of-sample section performance tend to average out to zero in the limit, leaving us with what to expect from our strategy and filter on average. Mathematical note: This assumption assumes that the out-of-sample returns are from probability distributions that have a finite variance.

Why use the walk forward technique? Why not just perform an optimization on the whole price series and choose the input parameters that give the best total net profits or profit factor? Surely the price noise cancels itself out with such a large number of in-sample trades. Unfortunately, nothing could be farther from the truth! Optimization is a misnomer and should really be called combinatorial search. As stated above, whenever we run a combinatorial search over many different combinations of input parameters on noisy data on a fixed number of prices, no matter how many, the best performance parameters found are guaranteed to be due to "curve fitting" the noise and signal. The price series that we trade consists of random spurious price movements, which we call noise, and repeatable price patterns (if they exist). When we run, for example, 5000 different inputs parameter combinations, the best performance parameters will be from those strategy input variables that are able to produce profits from the price pattern and the random spurious movements. While the price patterns will repeat, the same spurious price movements will not. If the spurious price movements that were captured by a certain set of input parameters were a large part of the total net profits, as they are in real intraday price series, then choosing
these input parameters will produce losses when traded on future data. These losses occur because the spurious price movements will not be repeated in the same way. This is why strategy optimization or combinatorial searches with no out-of-sample testing cause loses when traded in real time from something that looked great in the in-sample section.

In order to gain confidence that our input parameter selection method using the optimization output of the in-sample data will produce profits, we must test the input parameters we found in the in-sample section on out-of-sample data. In addition, we must perform the in-sample/out-ofsample analysis many times. Why not just do the out-of-sample analysis once or just 10 times? Well just as in Poker or any card game, where there is considerable variation in luck from hand to hand, walk forward out-of-sample analysis gives considerable variation in week-to-week out-ofsample profit ñuckò. That is, by pure chance we may have chosen some input parameter set that did well in the in-sample section data and the out-of-sample section data. In order to minimize this type of ñluckò, statistically, we must repeat the walk forward out-of-sample (oos) analysis over many ( $>50$ ) in-sample/out-of-sample sections and take an average over all out-of-sample sections. This average gives us an expected out-of-sample return and a standard deviation of out-of-sample returns which allows us to statistically estimate the expected equity and its range for N out-of-sample periods in the future

## Finding the Strategy Parameters Using Walk Forward Optimization

For the in-sample data we will run the TradeStation optimization engine on the 595 weeks of EC 1 min bars with the following ranges for the nth order fading memory polynomial velocity strategy input variables.

1. $\mathbf{p w}=$ degree $=\mathbf{2}$
2. N from 20 to 70 in steps of 10 .
3. vup from 0.25 to 3.5 steps of 0.25
4. vdn from 0.25 to 3.5 in steps of 0.25
5. Mult $=6200$, iNorm $=1$ (See Appendix 3, the Normalization Multiplier)

Note: I use $\mathbf{N}$ because it gives a better understanding of how many bars of past data are approximately being used.
$\mathbf{N}$ and $\alpha(\alpha=1-\beta)$ are approximately related by the formula $\alpha=\mathbf{2} /(\mathbf{1}+\mathbf{N})$. N is converted to $\alpha$ by this formula in the Nth Order Fading Memory Polynomial calculation

This will produce 1176 different cases or combinations of the input parameters for each of the 595 PWFO output files.

## Finding the Strategy Input Parameters in The Walk Forward Test Sections

The question we are attempting to answer statistically is which performance metric or combination of performance metrics (which we will call a filter) applied to the in-sample section will produce in-sample strategy inputs that produce statistically valid average profits in the out-ofsample section. In other words, we wish to find a performance metric filter that we can apply to the in-sample section that can gives us strategy inputs that will produce, on average, good trading results in the future.

When TS/MC does an optimization over many combinations of inputs, it creates an output page that has as its rows each strategy input combination and as itô columns various trading performance measures such as Profit Factor, Total Net Profits, etc. An example of a simple filter would be to choose the strategy input optimization row in the in-sample section that had the highest Net Profit or perhaps a row that had the best Profit Factor with their associated strategy inputs. Unfortunately, it was found that this type of simple metric performance filter very rarely produces good out-of-sample results. More complicated metric filters can produce good out-ofsample results minimizing spurious price movement biases in the in-sample selection of strategy inputs.

The combination metric filters are found by a program called WFME64v8x. Details of this program can be found at http://meyersanalytics.com/wfme.html.

All PWFO file metrics used by the WFME64v8x are described at http://meyersanalytics.com/Walk-Forward-Optimization.html .

We will use the WFME64 v8x program to find one in-sample combination-metric filter applied to each in-sample section which gives a set of strategy inputs which are then applied to each following out-of-sample section This will consist 543 in-sample and out-of-sample sections We will leave the 52 sections of EC data from 6/29/18 to 6/28/2019 out of the WFME64 calculations so that we can see how the metric filters found by the WFME64 performed on these 52 following future weeks which was not included in the original WFME64 run.

Here is the metric combination filter found by the WFME64 v8x program that was used in this paper. High profit factors ( $\mathbf{p f}$ ) in the in-sample section usually mean poor performance in the out-of-sample-section. This is a kind of reversion to the mean. So, in the in-sample (IS) section we eliminate all strategy input rows that have the in-sample metric $\mathbf{p f}>\mathbf{2}$. In addition, we wish to limit the number losing trades in a row ( $\mathbf{l r}$ ) in the IS period to 5 or less ( $\mathbf{l r} \leq 5$ ). $\mathbf{r} \mathbf{2}$ is defined as the insample trade equity regression trend line coefficient of correlation $\mathbf{r}^{2}$. High $\mathbf{r} 2$ values in the insample section usually mean poor performance in the out-of-sample-section. This is also a kind of reversion to the mean and a measure of how well the price noise is being fitted in the IS section. So, in the in-sample section we eliminate all strategy input rows that have a $\mathbf{r 2} \mathbf{> 5 0}$. Using the $\mathbf{p f}$ -lr-r2 elimination screen, as described, there can still be $100 \hat{0}$ of rows left in the in-sample section. The PWFO generates the performance metric named $\mathbf{n T}$. This metric is the number of trades in the in-sample section. Let us choose the 50 rows in the in-sample section that contain the minimum number of in-sample trades. nT (with the criteria that $\mathrm{nT} \geq 3$ ), values from the rows that are left from the $\mathbf{p f}-\mathbf{I r}-\mathbf{r} \mathbf{2}$ screen. In other words, we sort $\mathbf{n T}$ from low to high, eliminate the rows that have $\mathbf{n T}<\mathbf{3}, \mathbf{p f}>\mathbf{2}, \mathbf{l r}>5, \mathbf{r}>50$ and then choose the smallest $\mathbf{5 0} \mathbf{n T}$ rows ( $\mathbf{n T} \geq \mathbf{3}$ ) of whatever is left. This filter will now leave 50 cases or rows in the in-sample section that satisfy the above filter conditions. We call this filter $\mathbf{b 5 0 n T}|\mathrm{p} \leq 2| \mathbf{l r} \leq \mathbf{5} \mid \mathbf{r} \mathbf{2} \leq \mathbf{5 0}$ where $\mathbf{b 5 0 n T}$ means the bottom or minimum 50 nT with $\mathbf{n T} \geq \mathbf{3}$ rows left after the pf-lr-r2 in-sample row elimination. Suppose for this filter, within the 50 in-sample rows that are left, we want the row that has the lowest loss of the column metric called dd. dd is the drawdown in the in-sample section for a given set of inputs. We abbreviate this final filter as $\mathbf{b 5 0 n t}|\mathbf{p} \leq \mathbf{2}| \mathbf{I r} \leq \mathbf{5} \mid \mathbf{r} \mathbf{2} \leq \mathbf{5 0}$-dd. For each in-sample section
this filter leaves only one row in the in-sample section with its associated strategy inputs and following out-of-sample net profit in the out-of-sample section using the strategy inputs found in the in-sample section. This $\mathbf{b 5 0 n t}|\mathbf{p} \leq \mathbf{2}| \mathbf{r} \leq \mathbf{5} \mid \mathbf{r} \mathbf{2} \leq \mathbf{5 0}$-dd filter is then applied to each of the 543 insample sections between 2/8/2008 and 6/29/2018 (the 52 out-of-sample sections between 6/29/18-6/28/19 are withheld from the WFME in-sample filter run) which give 543 sets of strategy inputs that are used to produce the corresponding 543 out-of-sample performance results. The average out-of-sample performance is calculated from these 543 out-of-sample performance results. In addition, many other important out-of-sample performance statistics for this filter are calculated and summarized.

Figure 2 shows such a computer run along with a small sample of other WFME64 filter combinations that are constructed in a similar manner. Row 3 of the sample output in Figure 2 shows the results of the filter discussed above.

## Bootstrap Probability of Filter Results.

Using modern "Bootstrap" techniques, we can calculate the probability of obtaining our filter's total out-of-sample net profits by chance. Hereô how the bootstrap technique is applied. Suppose as an example, we have 500 files of in-sample/out-of-sample data. A mirror random filter is created. Instead of picking an out-of-sample net profit (OSNP) from a filter row as before, the mirror filter picks a random row's OSNP in each of the 500 files. We repeat this random picking in each of the 500 files 5000 times. Each of the 5000 mirror filters will choose a random row's OSNP of their own in each of the 500 files. At the end, each of the 5000 mirror filters will have 500 random OSNP's picked from the rows of the 500 files. The sum of the 500 random OSNP picks for each mirror filter will generate a random total out-of-sample net profit (toNP) or final random equity for each of the 5000 mirror filters. The average and standard deviation of the 5000-mirror filter's different random toNPs will allow us to calculate the chance probability of our above chosen filter's toNP. Thus, given the 5000-mirror filter's bootstrap random toNP average and standard deviation, we can calculate the probability of obtaining our chosen filter's toNP by pure chance alone. Figure 2 lists the 5000-mirror filter $\hat{Q}$ bootstrap average for our 543 out-of-sample files of ( $\$ 141.8$ ) with a bootstrap standard deviation of $\$ 48.9$. (Side Note. The average is the random average per out-of-sample period. So, the average for the random selection would be the random (Average Random toNP/543) and the average net weekly for the filter from Figure 2, Row 3 would be the filter toNP/ (\# of OOS) periods traded or $\mathbf{8 7 8 9 1} / \mathbf{4 0 0}=\mathbf{2 1 9 . 7 3}$. The probability of obtaining our filters average weekly net profit of $\mathbf{2 1 9 . 7 3}$ is $7.35 \times 10^{-14}$ which is 7.39 standard deviations from the random bootstrap average. For our filter, in Row 3, the expected number of cases that we could obtain by pure chance that would match or
 total number of different filters we looked at in the WFME64v8x run. This number is much less than one, so it is improbable that our filters result of 89891 was due to pure chance

## Results

Table 1 on page 8 below presents a table of the 595 in-sample and out-of-sample windows, the selected optimum parameters and the weekly out-of-sample results using the filter described above.

Figure 1 presents a graph of the equity curve generated by using the WFME64 filter on the 543 weeks ending $2 / 8 / 2008$ ï $6 / 29 / 18$ and the equity curve on the 52 weeks following until 6/28/2019 (note the starting date $1 / 2 / 2008$ was part of the first 30 day in-sample period). The equity curves are plotted from Equity and Net Equity columns in Table 1. Plotted on the equity curves is the $2^{\text {nd }}$ Order Polynomial curve. The blue line is the equity curve without commissions and the red dots on the blue line are new highs in equity. The brown line is the equity curve with commissions and the green dots are the new highs in net equity. The grey line is the ES weekly closing prices superimposed on the Equity Chart. The vertical dotted red line on the right separates the WFME run excluded period equity from $6 / 29 / 18$ to $6 / 28 / 19$. This is what would have happened if you used the strategy inputs found by the filter $\mathbf{b 5 0 n t}|\mathbf{p} \leq 2| \mathbf{I r} \leq \mathbf{5} \mid \mathbf{r} \mathbf{2} \leq \mathbf{5 0}$-dd on data not included in the initial WFME run

Figure 2 shows such a computer run along with a small sample of other WFME64 filter combinations that are constructed in a similar manner. Row 3 of the sample output in Figure 2 shows the results of the filter discussed above.

Figure 3 Walk Forward Out-Of-Sample Performance for EC Fading Memory Polynomial Velocity System
1 minute bar chart of EC from 12/4/15-12/4/2015

## Discussion of Strategy Performance of the WFME64 run

In Figure 2, Row 3 is the filter chosen, $\mathbf{b 5 0 n t}|\mathbf{p} \leq \mathbf{2}| \mathbf{l} \leq \mathbf{5} \mid \mathbf{r} \mathbf{2} \leq \mathbf{5 0}$-dd. This Metric Filter produced $\$ 87891$ net profits after costs in 543 weeks and $\$ 4022$ net profits after costs in the withheld 52 weeks from the initial WFME run. The spreadsheet columns present some statistics that are of interest for the filter. An interesting statistic is Blw. Blw is the maximum number of weeks the OOS equity curve for this filter failed to make a new high. Blw is 44 weeks for this filter. This means that 44 weeks was the longest time that the equity for this strategy failed to make a new equity high in the 543 out-of-sample weeks. For this strategy, the $\mathbf{\%} \mathbf{P}$ (\% of weekly oos periods that are positive) was $\mathbf{6 2 \%}$, and the $\% \mathbf{W t r}$ (The $\%$ of all oos trades that are positive) was $\mathbf{5 4 \%}$. This low $\% \mathbf{W} t r$ was made up for by $\mathbf{o W} / \mathbf{o L}$ (average oos winning trades/average oos losing trades) equal to 1.38 .

To see the effect of walk forward analysis, look at Table 1. Notice how the input parameters $\boldsymbol{N}$, $\boldsymbol{v u p}, \boldsymbol{v d} \boldsymbol{n}$ take sudden jumps from high to low and back. This is the walk forward process quickly adapting to changing volatility conditions in the in-sample sample. In addition, notice how often $\boldsymbol{N}$ changes from 10 to 70 . When the data gets very noisy with a lot of spurious price movements, the look back period, N, should be higher. During other times when the noise level is not as much N can be lower to get onboard a trend faster.

Using this filter, the strategy generated a profit of $\$ 91,913$ net equity after commissions and slippage of $\$ 20 /$ trade trading one EC contract for the total 595 weeks. From Table 1, the largest losing week was - $\$ 2313$ on the week ending 4/3/09. The largest drawdown was $-\$ 4989$ from the week ending on $12 / 11 / 09$ to $3 / 26 / 10$. This drawdown lasted 15 weeks and took 8 weeks to recover and make a new equity high. The future 52 -week period that was not included in the

WFME64 run from 6/29/18 to 6/28/19 was a volatile down market yet the FadmV strategy/WFME filter did well making a net profit of $\$ 4072$ during that one-year time frame.

Lastly. as can be seen in Figure 3, the top 10 filters all did very well in the 52 future weeks from $6 / 29 / 18$ to $6 / 28 / 19$ following the original analysis.

In observing Table 1 we can see that this strategy and filter made trades from a low of no trades in 143 of the 543 weeks to a high of 15 trades/week with an average of 2.3 trades/week in the weeks it did trade.

Given 24-hour trading of the Euro, restricting the strategy to trade only from 7am to 1:50pm caused the strategy to miss many profitable trends opportunities when Asia and then Europe opened trading in the early morning. Further research will include the A.M. time zones.

## WFME64 v8X AVE File Output Cols are defined as follows

## * Row 1:

Columns: A=The PWFO Stub, B=File Start Date, C=File End Date, D= Number of oos periods (in this example weeks), $\mathbf{K}=$ Minimum number of trades in IS section, $\mathbf{N}=$ Bootstrap average, $\mathbf{O}=$ Bootstrap Standard Deviation, $\mathbf{P}=$ Number of filters run, $\mathbf{U}=$ Cost and slippage per trade, $\mathbf{A B}=$ Not Included in WFME Run PWFO File Start Date, AC= Not Included in WFME Run PWFO File End Date, AD:=Number of PWFO Files not included in the WFME64 run (in this example weeks), AH= Number of Total PWFO Files.

## * Row 2 to Last Row Columns: A through AH

Col A: The Strategy Input/Filter Names Example Row 3: $\mathbf{b 5 0 n T}|\mathbf{p} \leq 2||\mathbf{r} \leq \mathbf{5}| \mathbf{r} \mathbf{2} \leq \mathbf{5 0}$-dd:
Col B: toGP - Total out-of-sample(oos) gross profit for these 543 oos periods (= weeks).
Col C: toNP - Total out-of-sample(oos) Net profit (toGP-Number of Trade Weeks*cost) for the 543 oos periods.
Col D: aoGP - Average oos gross profit for the 543 oos periods
Col E: aoTr - Average oos profit per trade
Col F: ao\#T - Average number of oos trades per week
Col G: std - he standard deviation of the 543 oos period profits and losses
Col H: skew - The Skew statistic of the 543 oos period profits and losses
Col I: kur - he kurtosis statistic of the 543 oos period profits and losses
Col J: $\boldsymbol{t}$ - The student t statistic for the 543 oos periods. The higher the t statistic the higher the probability that this result was not due to pure chance
Col K: oWloL - Ratio of average oos winning trades divided by average oos losing trades.
Col L: \%Wtr - he percentage if oos winning trades
Col M: \%P - percent of all oos periods that were profitable.
Col N : LLtr - The largest losing oos trade in all oos periods
Col O: LLp - The largest losing oos period

Col P: eqDD - The oos equity drawdown
Col Q: wpr - The largest number of winning oos periods (weeks) in a row.
Col R: Ipr - he largest number of losing oos periods in a row
Col S: \# - The number of oos periods this filter produced any profit or loss. Note for some oos periods there can be no strategy inputs that satisfy a given filters criteria and no trades will be made during that period.
Col T: v20 - The Velocity of a $2^{\text {nd }}$ order polynomial fit to the last 20 periods of the oos equity curve.
Col U: Dev^2 - measure of equity curve smoothness. The square root of the average (equity curve minus a straight line $)^{\wedge} 2$ )
Col V: KTau^2 - The Kendall rank coefficient is often used as a test statistic in a statistical hypothesis test to establish whether two variables may be regarded as statistically dependent. This test is non-parametric, as it does not rely on any assumptions on the distributions of $X$ or $Y$ or the distribution of $(X, Y)$
Col W: eqR2 - The correlation coefficient( $\left.\mathrm{R}^{\wedge} 2\right)$ of a straight-line fit to the equity curve.
Col X: Blw - The maximum number of oos periods the oos equity curve failed to make a new high.
Col Y: BE - Break even in oos periods. Assuming the average and standard deviation are from a normal distribution, this is the number of oos periods you would have to trade to have a $98 \%$ probability that your oos equity is above zero.
Col Z: tkr|bl = t*ktau*eqR2/Blw a measure of how good the filter fit is.
Col AB: toGPx Total gross profit for the 52 future excluded periods (for this run periods = weeks).
Col AC: toNPx Total Net profit \{toGP-Number of Trade Weeks(\#)*cost\} for the 52 future excluded periods.
Col AD: aoTrx Average profit per trade for the 52 future excluded periods
Col AE: aoNTx Average number of trades per week for the 52 future excluded periods
Col AF: \#x the number of the 52 future excluded periods this strategy/filter traded. Note for some periods there can be no strategy inputs/filter that satisfy the Strategy Inputs/Filter criteria and no trades will be made during that period.
Col AG: tOnpNet - toNP+toNPx = Total Net Profits of oos+future periods
Col AH: Prob - The probability that the filters toNP was due to pure chance.

Figure 3 Walk Forward Out-Of-Sample Performance for EC Fading Memory Polynomial Velocity System 1 minute bar chart of EC from 4/28/19-4/26/119

Table 1 Walk Forward Out-Of-Sample Performance Summary for EC 1-min Nth Order Fading Memory Polynomial Velocity System

EC-1 min bars 1/3/2008-06/28/2019. The input values degree(pw), $N$, vup, vdn are the values found from applying the filter to the in-sample section optimization runs.

Filter= : $\mathrm{b} 50 \mathrm{nT}|\mathrm{p} \leq 2||\mathrm{r} \leq 5| \mathrm{r} 2 \leq 50-\mathrm{dd}$
osnp = Weekly Out-of-sample gross profit in \$
Equity = Running Sum of weekly out-of-sample gross profits \$
NOnp\$20 = Weekly Out-Of-Sample Net Profit in \$ = osnp-ont*20.
NetEq = running sum of the weekly out-of-sample net profits in \$
ollt = The largest losing trade in the out-of-sample section in \$.
odd = The drawdown in the out-of-sample section in $\$$.
ont $=$ The number of trades in the out-of-sample week.
$\mathrm{pw}=$ degree, degree=$=1$ for straight line velocity, degree=2 for $2^{\text {nd }}$ order velocity, etc.
$\mathrm{N}=\mathrm{N}$ the lookback period
vup, the threshold amount that velocity has to be greater than to issue a buy signal
vdn, the threshold amount that velocity has to be less than to issue a sell signal
Note: Blank rows indicate that no out-of-sample trades were made that week

## Appendix 1: $\boldsymbol{n}^{\text {th }}$ Order Fading Memory Polynomial Next Bar's Forecast Math

## What is The $\mathbf{N}^{\text {th }}$ Order Fading Memory Polynomial?

This is a mathematical technique that fits a $\mathrm{n}^{\text {th }}$ order polynomial to the last $\boldsymbol{T}$ price bars but calculates the coefficients of the polynomial such that the error between the current $\mathrm{n}^{\text {th }}$ order polynomial and the current bar is weighted much higher than the error between the price T bars ago and the value of the $\mathrm{n}^{\text {th }}$ order polynomial T bars ago. As an example, if the latest price is at time t and the price made a turn at time bar $t-10$, then we do not want prices prior to $t-10$ affecting the current polynomial fit as much. As will be shown the most familiar case of this fading memory technique is the exponential moving average. The fading memory technique is in contrast to the Least Squares Polynomial fit, which weights all past errors between the polynomial and the price bar equally.

Consider a time series $x(t)$ where $t$ is an integer value (a price bar number) like the number of days or minutes, etc from some starting time. Suppose we want to find at some given time some $n$ th-degree polynomial that fits the data well at current and recent prices but ignores the fit as we move into the distant past. One way to construct this type of fit would be to weight the past data with a number that got smaller and smaller the further back in time we went. If we let the polynomial function be represented by the symbol $\mathbf{p}(\mathbf{t}-\tau)$ where $\mathbf{p}(\mathbf{t}-\mathbf{0})$ is the current value of the polynomial, $\mathbf{p}(\mathbf{t} \mathbf{- 1})$ is the previous value of the polynomial, etc., then an error function can be formed that consists of the weighted sum of the squared difference between the price series $\mathbf{x}(\mathbf{t}-\tau)$ and the polynomial $p(t-\tau)$ given by

$$
\text { error }=\Sigma \beta^{\tau}(\mathbf{x}(\mathbf{t}-\tau)-\mathbf{p}(\mathbf{t}-\tau))^{2} \quad \tau=\mathbf{0} \text { to } \infty
$$

where $\mathbf{0}<\beta<\mathbf{1}$ and $\beta^{\tau}$ is much much less than $\mathbf{1}$ for large $\tau$.
It turns out that if we let the $\mathrm{n}^{\text {th }}$ degree polynomial $\mathbf{p}(\mathbf{t}-\tau)$ be constructed as a linear combination of orthogonal polynomials called Meixner polynomials then minimizing the error with respect to the coefficients of the orthogonal polynomials yields the best estimate of $\mathbf{x}(\mathbf{t}-\tau)$ as $\mathbf{X e s t}(\mathbf{t}-\tau)$ and given by the equation

$$
\begin{equation*}
x_{e s t}(t-\tau)=\left.(1-\beta) \sum_{k=0}^{n} \beta^{k} b_{k, t} \Phi_{k}(t)\right|_{\tau} \tag{2}
\end{equation*}
$$

Where

$$
\begin{aligned}
\Phi_{n}(t) & =\sum_{k=0}^{n}\binom{n}{k}\binom{t}{k} z^{k} \\
\binom{n}{k} & =\frac{n!}{k!(n-k)!} \\
b_{j, t} & =\sum_{k=0}^{\infty} \beta^{k} \Phi_{j}(k) x(t-k) \\
\mathbf{z} & =\mathbf{1}-\mathbf{1} / \beta
\end{aligned}
$$

where n is the polynomial degree, $\Phi_{\mathbf{k}}(\tau)$ are the Meixner polynomials of degree $\mathrm{k}(\mathrm{k}=0$ to n$)$, and $\mathbf{b}_{\mathbf{k}}(\mathbf{t})$ are the coefficients that minimize the error of equation (1). Generally the summation for $\mathbf{b}_{\mathbf{j}}(\mathbf{t})$ can be terminated when $\beta^{\mathbf{k}} \ll 1$.

For the exact mathematical solutions that produce equation (2) and the mathematical descriptions of the Meixner polynomials refer to Reference 1.

To yield the 1 day ahead prediction the above equation becomes;

$$
\begin{equation*}
\mathbf{x e s t a}(\mathbf{t}+\mathbf{1})=(1-\beta) \sum \beta^{k} \mathbf{b}_{k, t} \Phi_{k}(-1) \quad k=0 \text { to } n \tag{3}
\end{equation*}
$$

After some algebraic manipulation with the Meixner polynomials the $\mathbf{b}_{\mathbf{k}, \mathbf{t}}$ coefficients satisfy the following recursive relationship.(see Reference 1)

$$
\mathbf{b}_{k, t}=\beta \mathbf{b}_{k, t-1}+\mathbf{b}_{k-1, t}-\mathbf{b}_{k-1, t-1}
$$

One case is of immediate interest where the polynomial is a constant, that is $\boldsymbol{n}=0$.
For this case the solution to equation (3) can be found after some algebraic manipulation to be:

$$
\begin{equation*}
\mathbf{X} 0_{\text {est }}=\beta * X 0_{\text {est }}[1]+(1-\beta) * x(t) \tag{4}
\end{equation*}
$$

Where $\mathbf{X} \mathbf{0}_{\text {est }}[\mathbf{1}]$ is the previous estimated value, $\mathbf{x}(\mathbf{t})$ is the current barôs price and where the 0 in $\mathbf{X} \mathbf{0}_{\text {est }}$ indicates that we are estimating a polynomial of degree 0 or simply a constant. If a change of variables is made letting $\alpha=(\mathbf{1}-\beta)$ then equation (4) becomes:

$$
\begin{equation*}
\mathbf{X} 0_{\text {est }}=(\mathbf{1}-\alpha) * \mathbf{X} \mathbf{0}_{\text {est }}[\mathbf{1}]+\alpha * \mathbf{x}(\mathbf{t}) \tag{5}
\end{equation*}
$$

This is the familiar formula for the exponential moving average.
Higher orders of $\boldsymbol{n}$ donâ yield such compact solutions as the case where $\boldsymbol{n}=0$.equations
$\mathbf{P}_{F}(\mathbf{T}+1)=(1-\beta)^{*}\left[b_{0, t} \phi_{0 \mid t=-1}+\beta \mathbf{b}_{1, \mathrm{t}} * \phi_{1 \mid \mathrm{t}=-1}+\beta^{2} \mathbf{b}_{2, \mathrm{t}} * \phi_{2 \mid t=-1}+\ldots+\beta^{n} \mathbf{b}_{\mathrm{n}, \mathrm{t}} * \phi_{n \mid t=-1}\right]$

Velocity $=\left(d P_{F} / d t\right)_{(T=-1)}=(1-\beta)\left[\beta b_{1, t}{ }^{*}\left(d \phi_{1} / d t\right)_{\mid t=-1}+\beta^{2} b_{2, t}^{*}\left(d \phi_{2} / d t\right)_{\mid t=-1}+\ldots+\beta^{n} b_{n, t}{ }^{*}\left(d \phi_{n} / d t\right)_{\mid t-1)}\right]$

## The $\mathbf{n}^{\text {th }}$ Order Fading Memory Forecast Next Bar's Velocity System Defined

The least squares forecast is constructed by solving for the coefficients $\mathbf{b}_{\mathbf{0}}, \mathbf{b}_{\mathbf{1}}, \mathbf{b}_{\mathbf{2}},,, \mathbf{b}_{\mathbf{n}}$ recursively at each bar using the last $\mathbf{T}$ bars of closing prices and the Discrete Orthogonal Meixner Polynomial equations above. Then Velocity $=\mathbf{d} P_{\mathbf{F}}(\mathbf{T}+\mathbf{1}) / \mathbf{d t}$ is constructed from the velocity equation above and plotted under the price chart. In general what we will be doing is following the plotted curve of Velocity which is calculated at each bar from the previous T bars. When the velocity is greater than a threshold amount vup we will go long. When the velocity is less than a threshold amount $\boldsymbol{v} \boldsymbol{v} \boldsymbol{d} \boldsymbol{n}$ we will go short.

## Buy Rule:

IF Velocity is greater than the threshold amount vup then buy at the market.

## Sell Rule:

IF Velocity is less than the threshold amount $\boldsymbol{- v} \boldsymbol{d} \boldsymbol{n}$ then sell at the market.

## What is the Multiplier ?

The $n^{\text {th }}$ Order Fading Memory Polynomial, also called here an $n^{\text {th }}$ Order Polynomial, is the least square fit of a polynomial of the form $\mathbf{P}_{F}(\mathbf{T}+1)=(1-\beta)^{*}\left[\mathbf{b}_{0, t} \phi_{0 \mid t=-1}+\beta \mathbf{b}_{1, t} * \phi_{1 \mid t=-1}+\beta^{2} \mathbf{b}_{2, t} * \phi_{2 \mid t=-1}+\ldots+\beta^{n} \mathbf{b}_{n, t} * \phi_{n \mid t=-1}\right]$ to a Fading number of past data points. Where $\mathbf{t}$ is discrete time bars. Time could be daily bars or one minute bars. We use the term ñFading Memoryò because we weight the past data with a number that gets smaller and smaller the further back in time we go. It is assumed that the time bars occur at fixed intervals of time so tic bars would not be appropriate for this analysis. Suppose we want to find at some given time some $n$ th-degree polynomial that fits the data well at current and recent prices but ignores the fit as we move into the distant past. One way to construct this type of fit would be to weight the past data with a number that got smaller and smaller the further back in time we went. This type of error minimization is mathematically solvable and is widely used in science and mathematics. Once the $\mathbf{b}_{\mathbf{n}}$ coefficients are found then the next barôs estimate ( $\mathbf{T}+\mathbf{1}$ ) of the $\mathrm{n}^{\text {th }}$ order polynomial Acceleration and acceleration can be easily found by the equations below.

$$
\begin{aligned}
& \text { Velocity }=\left(d P_{F} / d t\right)_{(T=-1)}=(1-\beta)\left[\beta \mathbf{b}_{1, t} *\left(d \phi_{1} / d t\right)_{\mid t=-1}+\beta^{2} \mathbf{b}_{2, t} *\left(d \phi_{2} / d t\right)_{\mid t=-1}+\ldots+\beta^{n} b_{n, t} *\left(d \phi_{n} / d t\right)_{\mid t=-1}\right] \\
& 0<\beta<1
\end{aligned}
$$

Please see the $\boldsymbol{n}^{\text {th }}$ Order Fading Memory Polynomial Next Bar's Forecast Math section for a more detailed explanation.

For any tradable, the inputs to the polynomial are the polynomial degree(aka Order) and exponential decay constant $\beta$. When we plot the velocity we notice that the amplitude, and the maximum and minimum values of and standard deviation of the velocity vary quite significantly with different polynomial degree and $\beta$ inputs.

Below is a table of the standard deviation of the 304156 calculated Velocity values for different degree and $\beta$ inputs. The lookback period $\mathbf{N}$ (number of bars of past data) is approximately related to $\alpha(\alpha=1-\beta)$ by the formula $\alpha=\mathbf{2} /(\mathbf{1}+\mathbf{N})$. I use $\mathbf{N}$ because it gives a better understanding of how many bars of past data are approximately being used. We used 1 min bars of the E-Mini from 5/1/2012 to 5/1/2015 to generate this table.

The standard deviation varies from 0.06 to 0.28 . The problem may get worse when we want to find good inputs for other tradables. Other tradables, because of their scales and tick size have much different Velocity ranges then the E-Mini for the same degree and $N$. Thus the search ranges have to be different for each different tradable, N and degree.

To solve this problem and to have a standard search space for each tradable, I created a Mult input for each FadmV Velocity strategy and indicator .. If each tradableôs Velocity is multiplied by a number such that the standard deviation of that tradableô Velocity is close to one standard deviation then the search space for vup and vdn for each tradable would be 0 to 3 standard deviations and we wouldnâ have to change the optimization search space every time we wanted to examine a new stock or future. The complicated equations that I use to normalize the ranges to one standard deviation for degree and N were derived using the software TableCurve 3D, automated surface and equation discovery. These equations are independent of the tradable and only depend on the polynomial degree and N . If you do not wish to use these equations then set iNorm=0. See note below .

## How to Find The Mult.

Here is how to use the \#FadmVMultStd. First load your chart with as much data as you are going to use. Click on Insert-> Indicator. Select the \#FadmVMultStd. Modify the inputs to the indicator or just leave them at their default values. A table will be produced as shown below.

| 4 | 70 | 0.3555 | 2.81294 | 0.999376 |
|  |  | pw=4 Ave | 2.85253 |  |
|  |  |  |  |  |
|  |  | Mult= |  | 2.81118 |

For each tradable chart:

1. Apply the FadmVMultStd indicator to your chart.
2. Find the Multiplier as shown above.
3. Record the multiplier value and delete the indicator from your chart.
4. Apply that multiplier to the Mult input with iNorm=1 in the strategy.
5. Do the parameter search for vup \& vdn in the default range 0.25 to 3 by 0.25 .

Added Note:
The complicated equations that I use to normalize the ranges to one standard deviation were derived using the software TableCurve 3D, automated surface and equation discovery. These equations are independent of the tradable and only depend on the polynomial degree and N. If you do not wish to use these equations then set inorm $=0$. Then when you run FadmVMultStd with inorm $=\mathbf{0}$ you will get a multiplier that gives an average of all the ranges. With iNorm=0 you will have to determine the vup -vdn ranges for your optimization. They will be different for different tradables and time bars. Below is the output for iNorm=0 for FadmVMultStd. As you can see the variation for degree $(\mathrm{pw})=2$ is 6 times the variation for degree=4. And the variation for $\mathrm{n}-$ 70 is five times the variation for $\mathrm{N}=20$. so for this example in order to cover all degree and N ranges at 3 standard deviations maximum you would have to go from vup/vdn from 0.0005 to 0.09 . Of course the best solution for iNorm=0 would be to modify the strategy multiplier for each degree and N which is essentially what my equation does but not as exact.
